

Brain Science and Addiction

NCLS Opioid Policy Fellows

Second meeting: evidence and innovations

Wednesday June 13th, 2018

Joseph Sakai, MD

Associate Professor

Division of Substance Dependence, Department of Psychiatry

University of Colorado School of Medicine

Conflicts of Interest: Dr. Sakai received reimbursement in 2012 for completing a policy review for the WellPoint Office of Medical Policy & Technology Assessment (OMPTA), WellPoint, Inc., Thousand Oaks, CA. He also served as a board member of the ARTS (Addiction Research & Treatment Services) Foundation until 2015.

Lab sources of support:

The Kane Family Foundation and the Hewit Family Foundation.

National Institute on Drug Abuse (R01DA031761, R25DA033219, DA009842, DA011015).

Defining terms...what is addiction?

Is it the amount used?

Frequency of use?

Is it something else?

Addiction, substance use disorder:

Substance Use Disorder

- Role failures
- Hazardous use
- Interpersonal problems
- More than intended
- Cut down
- Time spent
- Activities limited
- Use despite consequences
- Tolerance
- Withdrawal
- Craving

2-3 mild;
4-5 moderate;
≥6 severe

Common in general population

	Alcohol abuse	Alcohol dependence	Drug abuse	Drug dependence
Lifetime	17.8%	12.5%	7.7%	2.6%
12-month	4.7%	3.8%	1.4%	0.6%

Grant et al Arch Gen Psychiatry 61: 361-368 J Clin Psychiatry 66:677-685
 Hasin, D. S. et al. Arch Gen Psychiatry 2007;64:830-842.
 Compton, W. M. et al. Arch Gen Psychiatry 2007;64:566-576

Even more prevalent in clinical populations...

COMORBIDITY (odds ratios – alcohol dependence):

	Men	Women
■ Depressive symptoms	2.7	4.1
■ Manic symptoms	8.1	4.7
■ Generalized anxiety symptoms	3.7	2.8
■ Social anxiety symptoms	2.0	2.6
■ Post-traumatic stress sx's	2.7	3.4

Kessler et al Arch Gen Psychiatry 54(4): 313-321

Even more prevalent in clinical populations...

General medical clinics

- 1/5 non-tobacco substance abuse problem

Inpatient medical services

- 23% current smokers
- 14% alcohol misuse
- 12% drug misuse

Common also in ED setting

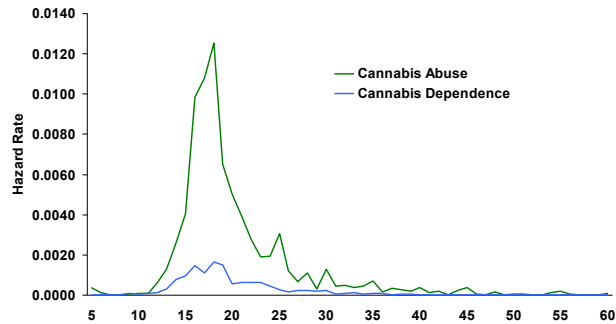

Cherpitel & Ye, Drug & Alcohol Dependence 2008; 97:226-230
Mercy, 2003
Kouimtsidis et al., 2003

With a common onset in adolescence...

Age at onset of alcohol dependence from Li et al.,
Biological Psychiatry 56:718-20

With a common onset in adolescence...

Age at onset of cannabis abuse and dependence – from Grant Psychological Medicine 36:1447-1460.

Age at onset of cocaine abuse and dependence – unpublished data

Common cause of preventable death...

Preventable causes of death in 1990:

#1 Tobacco (400,000 deaths per year)

#3 Alcohol (100,000 deaths per year)

#9 Illicit drugs (20,000 deaths per year)

Actual causes of death in 2000:

#1 Tobacco (435,000 deaths per year)

#3 Alcohol (85,000 deaths per year)

#9 Illicit drugs (17,000 deaths per year)

Mokdad et al. JAMA 2004; 291:1238-45

Dramatic rise in drug-related deaths...

Total U.S. Drug Deaths

Total U.S. Drug Deaths* - More than 64,000 Americans died from drug overdoses in 2016, including both drugs and prescription opioids.
*Includes deaths in all states. Source: CDC WONDER

Historically, physicians have not consistently addressed addiction...

Physicians generally – poor job of screening

Survey of FP's (n=648)

90% failed dx substance abuse when presented with early symptoms of alcohol abuse in an adult patient

40% of pediatricians presented with classic description of drug abusing teen – did not include substance abuse in their differential

Another study in primary care practices – patients with alcohol dependence received assessment and referral to treatment only 10% of the time

Only about 3% of those with alcohol use disorder in past 12-months report that they had received help from a physician or other health care professional

McGlynn et al. NEJM 2003; 348:2635-2645
Hasin, D. S. et al. Arch Gen Psychiatry 2007;64:830-842
National Center on Addiction and Substance Abuse, 2000

A biological basis...

- A disorder historically relatively ignored...
- More difficult to have compassion for...self-induced vs. a victim...a behavioral component.
- Not a “moral failing” or “willful misconduct”

A biological basis...

Figure 2. Relative risks of substance dependence in first- to fifth-degree relatives, given that the index person is dependent on the same substance. The 95% confidence intervals are provided as error bars for each RR estimate. (In color in *Assadd* online.)

Tyrfingsson et al., 2010

A biological basis...

- Twin and adoption studies ~50% of variance in the population related to genes
- Animal studies –
 - rats become addicted to the same substances that humans do
 - rats can be bred to create strains that are likely to become quickly and severely (measured in level presses/dose) addicted to substances

Cloninger, 1999; *American Journal on Addictions* 9: 285

A biological basis...

Table 2. Relative risks for substance disorders

Substance A	NA	Substance B	NB	Mates
Alcohol	15,361	Alcohol	15,361	3.40 [3.23, 3.59]
Cannabis	3185	Cannabis	3185	14.48 [12.41, 16.97]
Sedatives	1759	Sedatives	1759	6.24 [4.61, 8.10]
Amphetamine	1619	Amphetamine	1619	19.42 [15.67, 29.46]
Cannabis	3185	Alcohol	15,361	6.52 [5.99, 7.08]
Sedatives	1759	Cannabis	3185	9.32 [7.79, 11.11]
Sedatives	1759	Alcohol	15,361	3.81 [3.47, 4.18]
Amphetamine	1619	Sedatives	1759	13.32 [10.88, 16.30]
Amphetamine	1619	Cannabis	3185	14.39 [12.23, 16.89]
Amphetamine	1619	Alcohol	15,361	6.60 [5.96, 7.30]

RR values reflect the risk of dependence on substance B observed in mat
For each condition the number of cases is provided, and the 95% confid

Tyrfingsson et al., 2010

Many youths try substances of abuse, why do some progress to a clinical diagnosis of a substance use disorder?

Pre-Existing Risk:

- N=1,000
- Enrolled from birth to age 32 years
- Self Control - 3, 5 yrs observational; 5, 7, 8, 11 parent, teacher and self report of impulsive aggression, hyperactivity, lack of persistence, inattention, and impulsivity.

Behavioral Disinhibition: Liability for Externalizing Spectrum Disorders and Its Genetic and Environmental Relation to Response Inhibition Across Adolescence

Sean E. Young, Naomi P. Friedman, Akira Miyoko, Erik G. Willcutt, Robin P. Corley, Brett C. Haberstick, and John K. Hewitt
University of Colorado at Boulder

Behavioral disinhibition has been characterized as a generalized vulnerability to externalizing disorders. Despite increasing evidence for its validity and heritability, the structural stability of behavioral disinhibition across adolescence and the strength and topology of its relation to executive functions have not been studied. In this twin-family twin study, the within-person behavioral disinhibition among monozygotic twins was unrelated to conduct disorder, attention-deficit/hyperactivity disorder (ADHD), and novelty seeking at ages 12 and 13. Executive functions were associated with laboratory-based cognitive tasks at age 17. Results indicated that, at age 12, behavioral disinhibition was dominated by ADHD and conduct problems and was highly heritable. At age 17, the contribution of the 2 components was more balanced, and the proportion of variance attributable to genetic factors was somewhat smaller, with additional variance due to shared environmental influences. At both ages, behavioral disinhibition was more closely related to response inhibition than other executive functions (working memory updating and task set shifting), and this relationship was primarily genetic in origin. These results highlight the dynamic nature of behavioral disinhibition across adolescence and suggest that response inhibition may be an important mechanism underlying vulnerability to disinhibitory psychopathology.

Keywords: executive control, disruptive behavior, impulsivity, ADHD, comorbidity

Since Gottesman and Newmann (1980) coined the term *disinhibitory psychopathology* and hypothesized an underlying diathesis and a neurobiological framework for this broad deficit in behavioral control, nearly 3 decades of research has documented the comorbidity among a wide range of behavioral problems that seem to fall under this rubric. The idea that behavioral disinhibition constitutes a generalized vulnerability to externalizing disorders has gained wide currency and consistent empirical support (Cicchetti, Maffei, & McClure, 2000), and the genetic nature of individual differences in behavioral disinhibition has also been demonstrated (Krause et al., 2002; Young, Willcutt, Corley, Hewitt, & Hewitt, 2008). Despite this progress, the nature of the developmental changes in behavioral disinhibition and its cognitive underpinnings remain subjects of intensive research efforts.

How stable are the structure and etiology of behavioral disinhibition across development? Although the phrase *behavioral disinhibition* includes the term *inhibition*, it is rarely related to individual differences in laboratory-based inhibition. If so, to what extent is that commonality attributable to genetic (as opposed to environmental) factors?

In this article, we report on a twin-family twin study designed to address these questions by focusing on the relationship between behavioral disinhibition and executive functions, a set of control processes that monitor and regulate lower-level cognitive processes and thereby shape complex thought and behavior. We assessed behavioral disinhibition at two points during adolescence (ages 12 and 17 years old), when a wide range of disinhibitory behaviors are manifested with increasing prevalence. Our guiding hypothesis is that deficits in one component of executive control,

Adolescent-onset SD:

Pre-Existing Risk:

12-14 years, very limited substance use; Scanned using Go/No-Go at baseline
 Followed into adolescence and categorized based on progression to heavy substance use

Norman et al., DAD 2011

Adolescent-onset SUD:

Lejuez et al. J Exp Psychol Appl 2002; 8:75
 Crowley et al., J Am Acad Child Adolesc Psychiatry 2006; 45:175

Figure 1. Negative relationship between brain activation and externalizing behavior scores. Children 9-11 years old are imaged as they decide to take risks. Significant areas include the reward-related circuitry (including midbrain and bilateral caudate and nucleus accumbens) and frontal regions (including inferior frontal gyrus superior frontal gyrus and cingulate gyrus).

Adolescent-onset SUD:

Laboratory studies using various modalities such as:

- Delay discounting
- Measures of impulsivity
- Measures of inhibition
- Measures of executive function
- Emotion regulation and anger

Show that adolescent patients with SUD perform more poorly than controls.

A biological basis...

- We are not all equally likely to develop a substance use disorder...some pre-existing risk
- What brain changes are associated with developing addiction...

DRUGS OF ABUSE TARGET THE BRAIN'S PLEASURE CENTER

Brain reward (dopamine) pathways

These brain circuits are important for natural rewards such as food, music, and sex.

Drugs of abuse increase dopamine

Typically, dopamine increases in response to natural rewards such as food. When cocaine is taken, dopamine increases are exaggerated, and communication is altered.

Brain Development:

Reward-related behavior:

Sullivan &
Pfefferbaum
Alcohol Alcohol
2009; 44:155

Inhalant-related brain injury:

- Toxic Leukoencephalopathy

Filley et al., NEJM 2001; 345(6):425

Adolescent-onset SD:

The adolescent brain may be particularly vulnerable to substance induced damage

Crews & Boettiger Pharmacol Biochem Behav 2009; 93:237

Adolescent-onset SUD:

Not all youths are equally likely to develop SUD

Problems of inhibition, high novelty seeking, poor delay discounting, affective regulation and rewards sensitivity etc. are related to increased risk

Early data suggest less GM volume and hypoactivation in both reward related pathways and frontal control circuits in those at risk or with early SUD

Exposure to substances then causes further brain changes in both reward, frontal control circuits and circuits important to stress, memory and learning

The Future:
